

Improve my RIS file project

Scope

- Proof of concept of sharing meta-data from existing repositories
- “Meta-data” is the added value of “appraised” evidence products
- The focus is
 - not on RIS, (i.e. can be RIS, CSV, Jason (HL7 FHIR))
 - But on building a shared knowledge base.

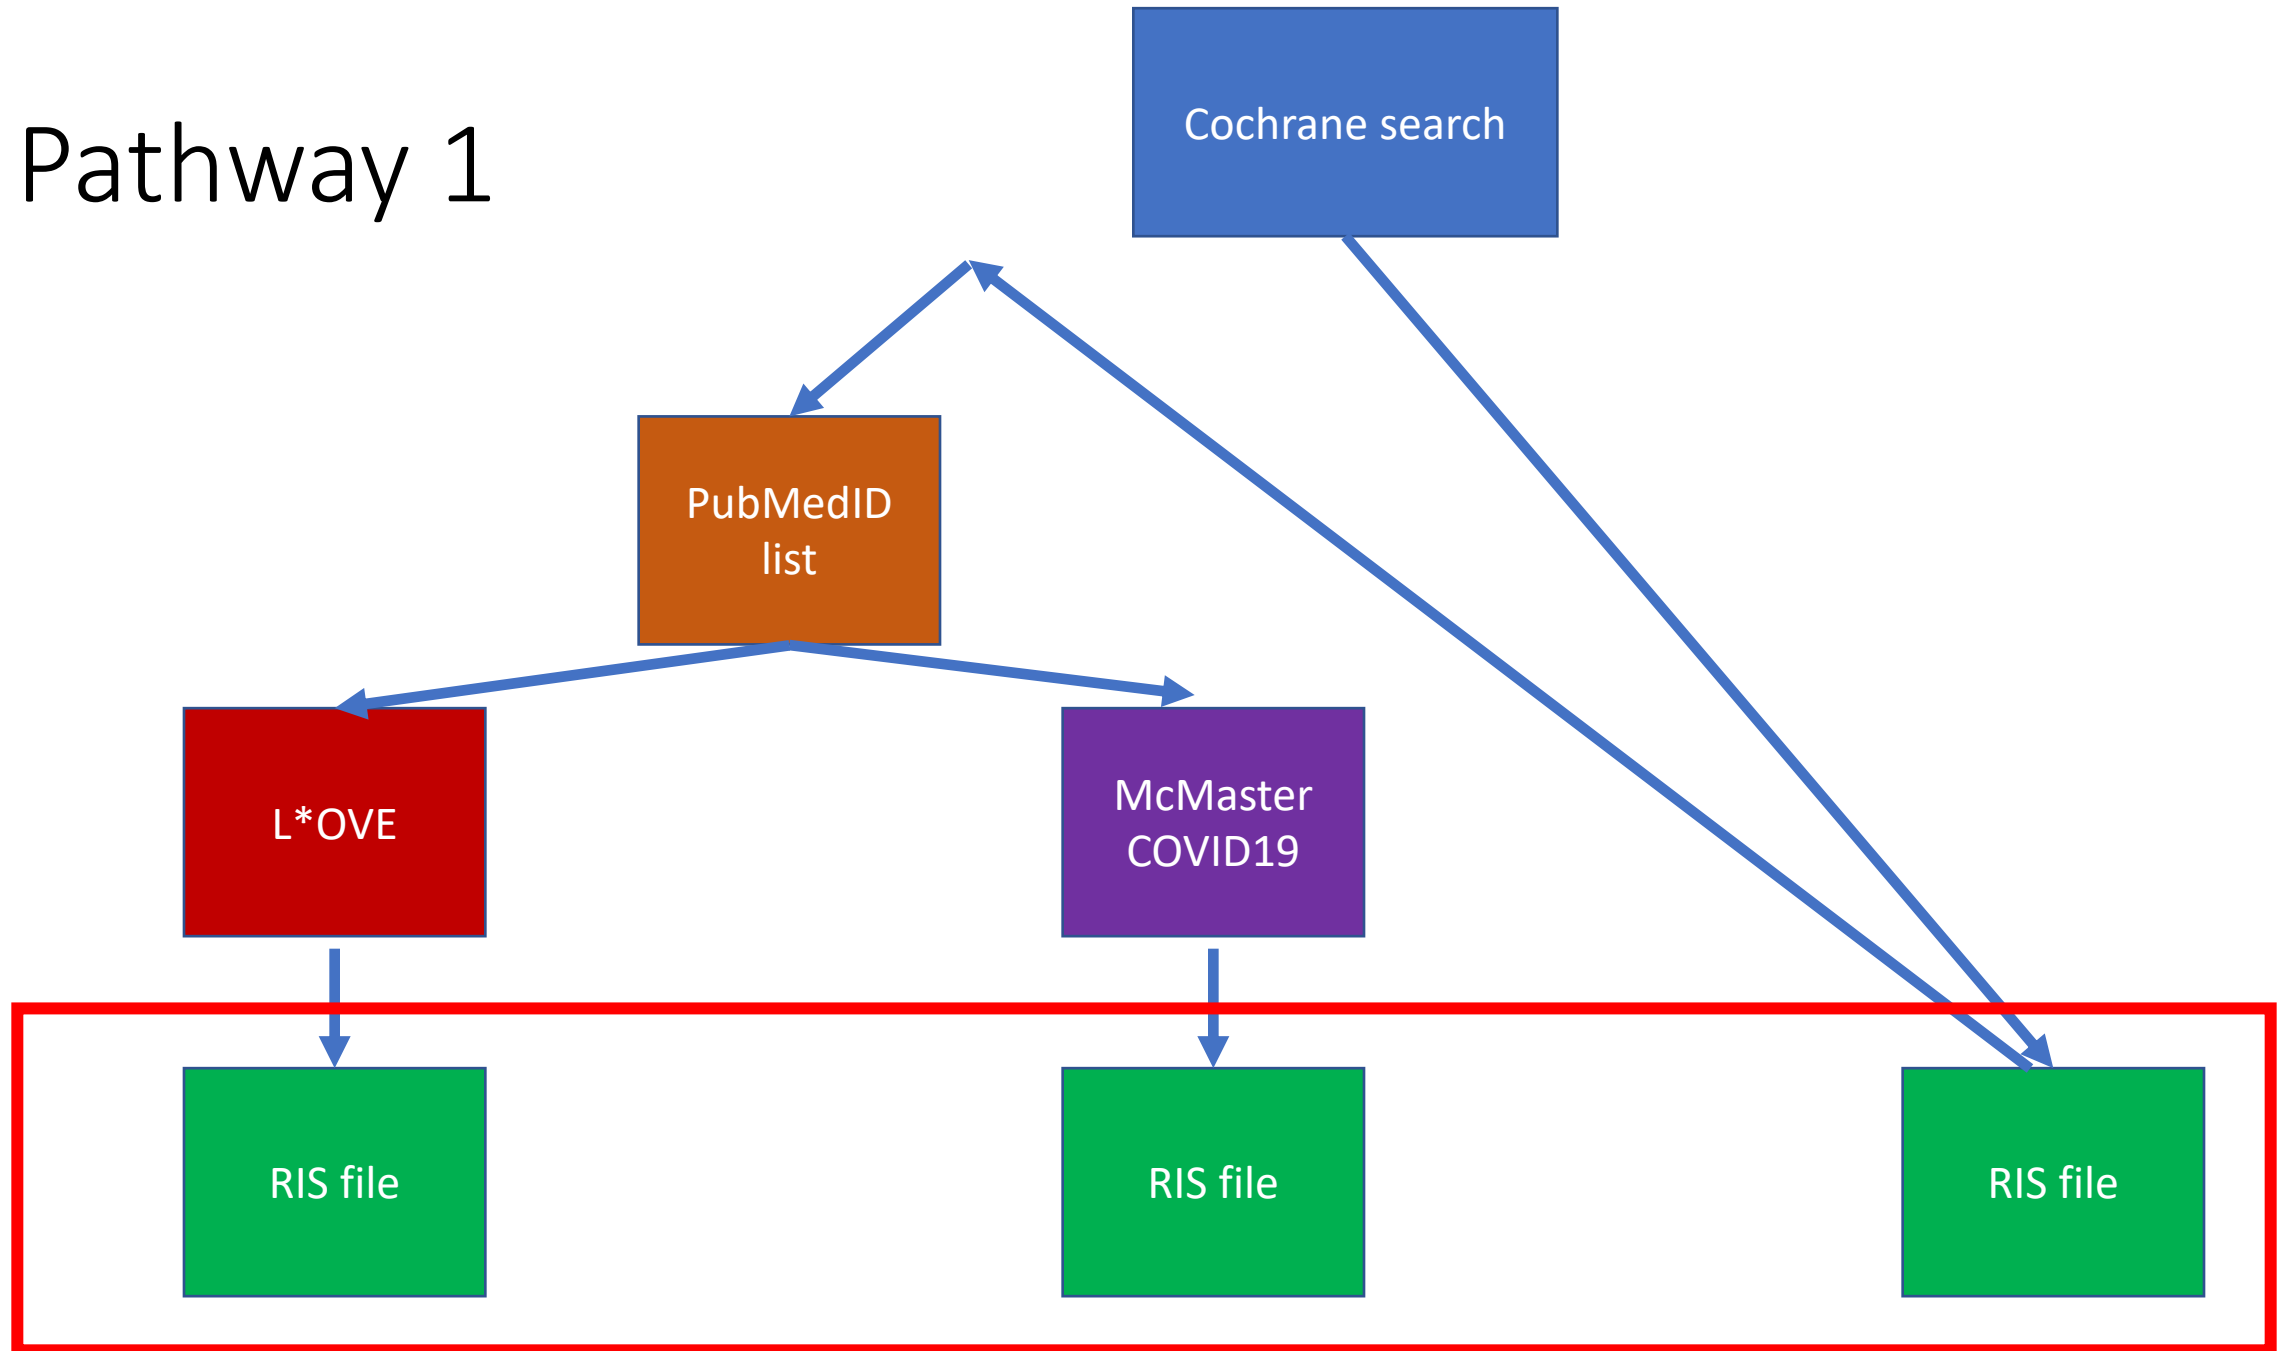

What does this address and what does it not address?

- It is a proof of concept for and approach to:
 - Obtaining meta-data for records from existing repositories
- It does not address:
 - Comprehensive searching (retrieving all references from all databases)
 - Federated searching (searching multiple databases at the same time)
 - De-duplication, or finding references unique to each repository
- It is a starting, not final point

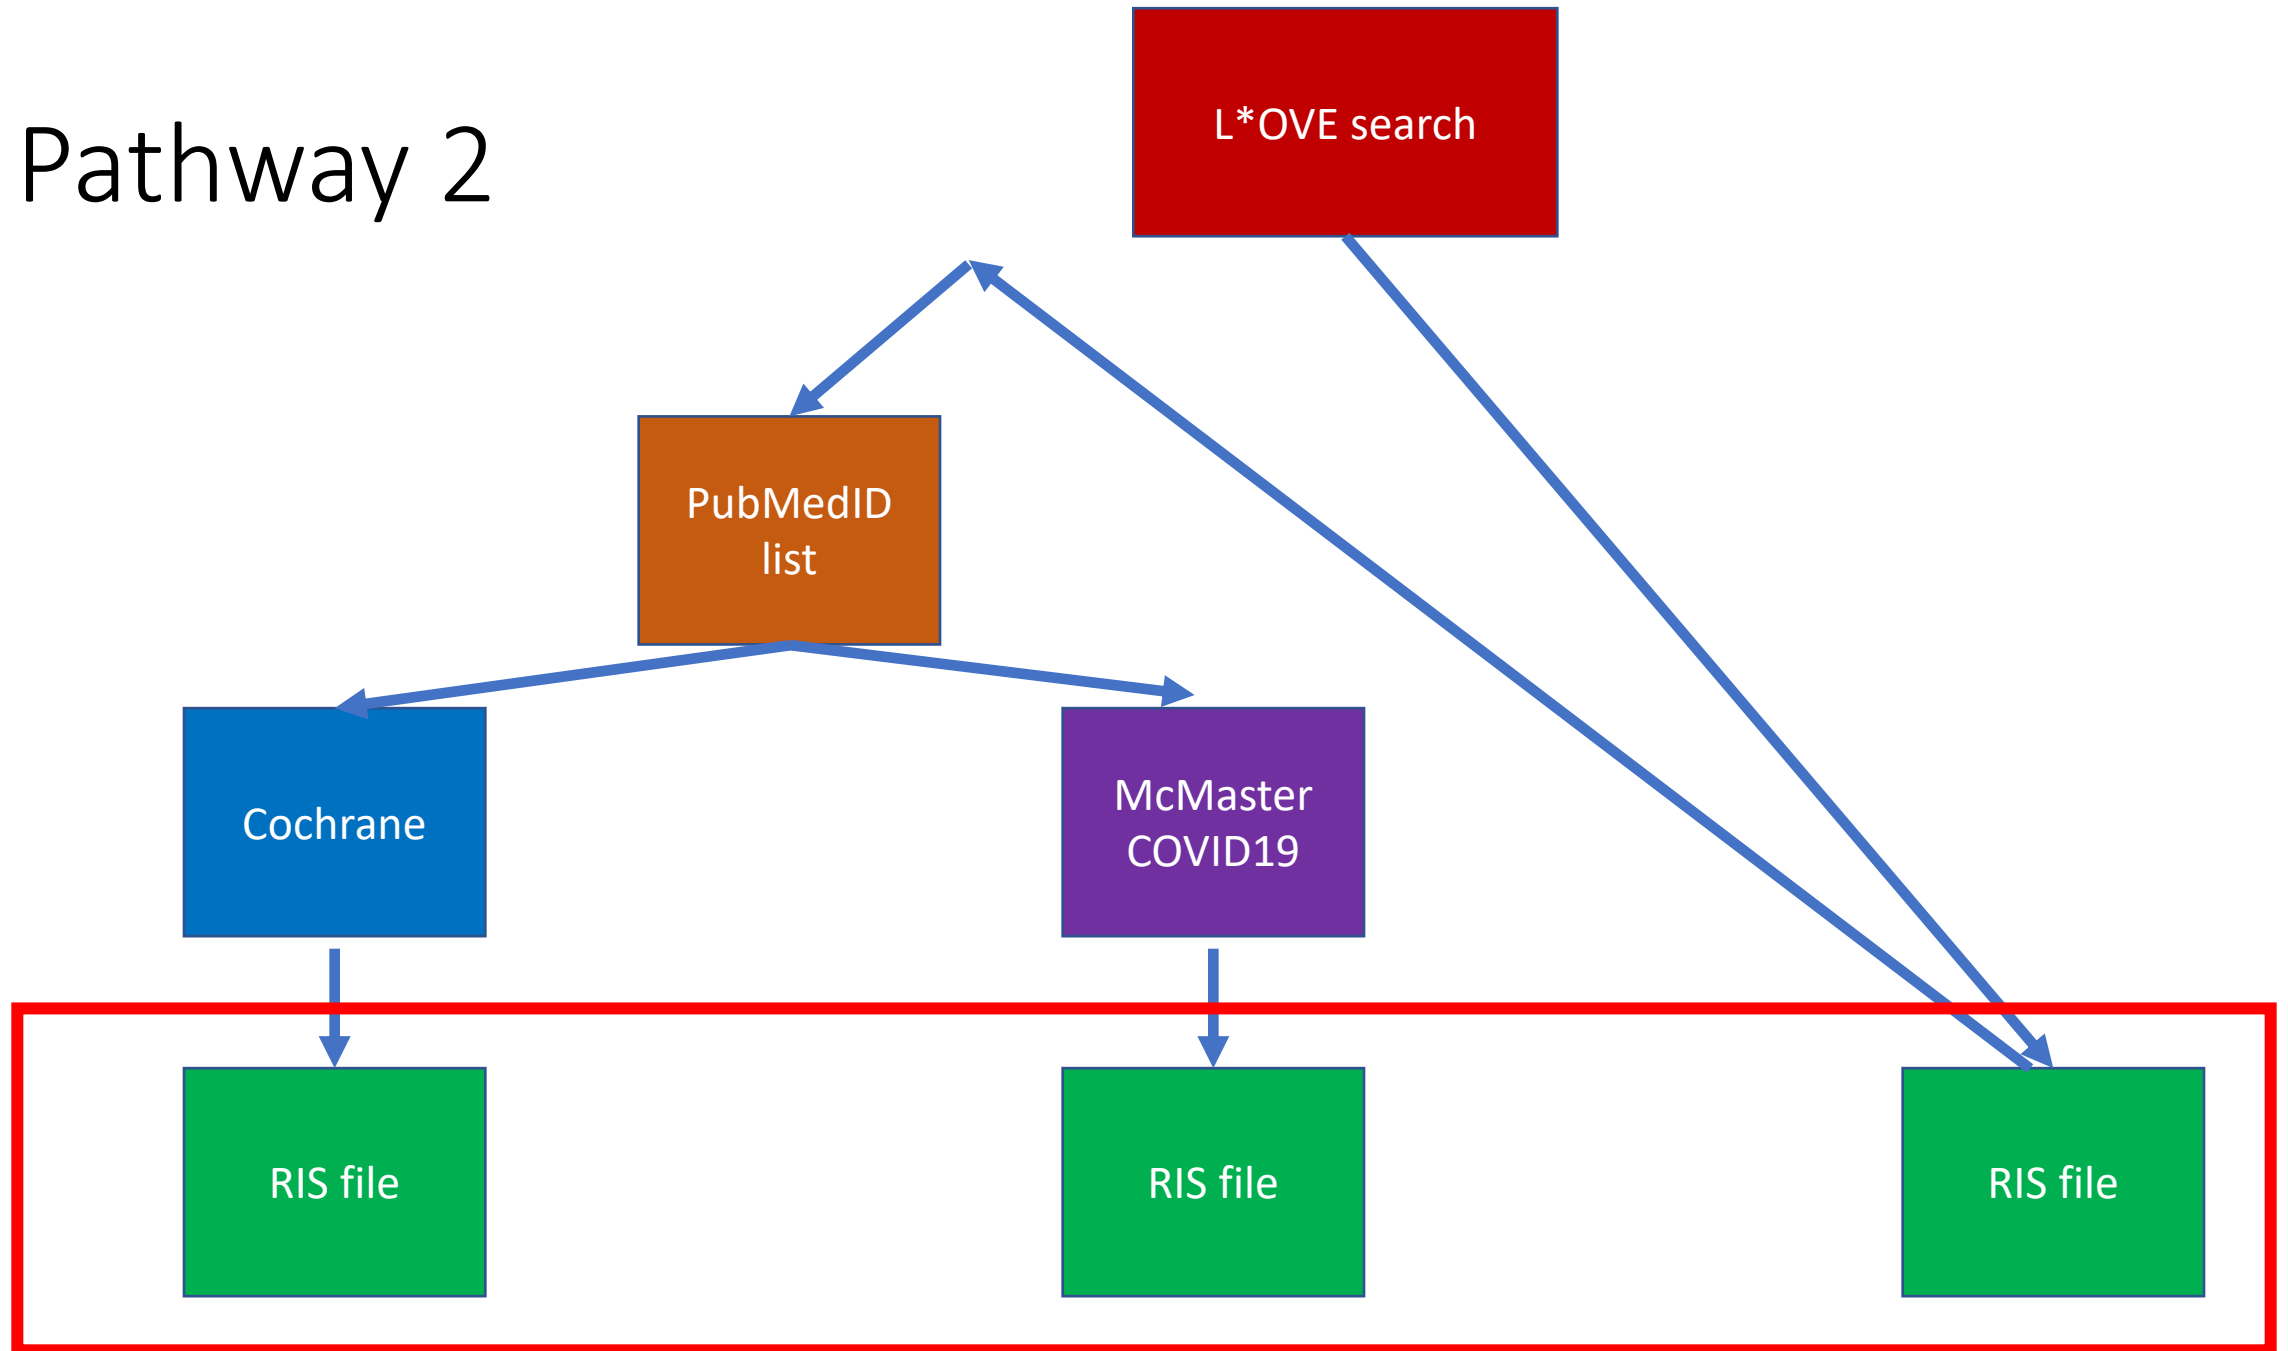

Worked example

- Performing/updating a review on the value of quarantine
- Search string:
 - quarantine isolation lockdown “lock down” cordon
“community containment” “containment area”
- Background:
 - ORing the terms on PubMed: 2,034,420 results
 - ANDing COVID19: 3,736 results

Pathway 1

Pathway 2

End-result: merged RIS

PMID	C-D	E-D	P-D	C-PICO	E-used in SR	P-quality grade
1	RCT	RCT	RCT			
2	Obs	Non-RCT	Obs			
3	Modeling	Non-RCT	Obs			
4	...					
5					

Still to agree on:

- Which field to export
- How to code them

- RIS vs CSV
- FIHR Json

RIS/CSV/Json availability is the base for building a RIS/CSV/json “manager” to automate querying, merging, de-duplication, etc

Pathway 1

Trusted evidence.
Informed decisions.
Better health.

quarantine isolation lockdown "lock down" cordon "community containment" "containment area"

The purpose of this study is to evaluate the effect of a range of interventions to improve outcome ofon patients admitted to intensive care with community-acquired pneumonia.

In addition, REMAP-CAP provides and adaptive research platform for evaluation of multiple treatment modalities in the event of a respiratory pandemic resulting in critical illness.

TI - Community-Acquired Pneumonia : Evaluation of Corticosteroids
 A1 - University Hospital, Tours
 PY - 2015

POPULATION

KW - Cortisol succinate // Hydrocortisone // Hydrocortisone 17-butyrate 21-propionate // Hydrocortisone acetate // Pneumonia
 T2 - ClinicalTrials.gov
 UR - https://clinicaltrials.gov/show/NCT02517489

INTERVENTION

AB - Mortality of severe Community-Acquired Pneumonia (CAP) has not declined over time and is between 25 and 30% in sub-groups of patients. Corticosteroids (CTx) could down-regulate pulmonary and systemic inflammation, accelerate clinical resolution and decrease the rate of inflammation-associated systemic complications. Two recent meta-analyses suggest a positive effect on severe CAP day 28 survival when CTx are added to standard therapy. However they are based on only four trials gathering less than 300 patients, of which only one was positive. Recently published guidelines do not recommend CTx as part of CAP treatment. Therefore a well-powered trial appears necessary to test the hypothesis that CTx - and more specifically hydrocortisone - could improve day 28 survival of critically-ill patients with severe CAP, severity being assessed either on a Pulmonary Severity Index ≥ 130 (Fine class V) or by the use of mechanical ventilation or high-FiO2 high-flow oxygen therapy.

OUTCOME

A phase-III multicenter add-on randomized controlled double-blind superiority trial assessing the efficacy of hydrocortisone vs. placebo on Day 28 all-causes mortality, in addition to antibiotics and supportive care, including the correction of hypoxemia.

Randomization will be stratified on: (i) centers; (ii) use of mechanical ventilation at the time of inclusion.

Abstract

About this article

Related evidence

An outbreak of respiratory illness proved to be infected by a 2019 novel coronavirus, officially named Coronavirus Disease 2019 (COVID-19), was notified first in Wuhan, China, and has spread rapidly in China and to other parts of the world. Herein, we reported the first confirmed case of novel coronavirus pneumonia (NCP) imported from China in Taiwan. This case report revealed a natural course of NCP with self-recovery, which may be a good example in comparison with medical treatments.

AB - Novel Coronavirus (2019-nCoV [SARS-COV-2]) was detected in humans during the last week of December 2019 at Wuhan city in China, and caused 24 554 cases in 27 countries and territories as of 5 February 2020. The objective of this study was to estimate the risk of transmission of 2019-nCoV through human passenger air flight from four major cities of China (Wuhan, Beijing, Shanghai and Guangzhou) to the passengers' destination countries. We extracted the weekly simulated passengers' end destination data for the period of 1-31 January 2020 from FLIRT, an online air travel dataset that uses information from 800 airlines to show the direct flight and passengers' end destination. We estimated a risk index of 2019-nCoV transmission based on the number of travellers to destination countries, weighted by the number of confirmed cases of the departed city reported by the World Health Organization (WHO). We ranked each country based on the risk index in four quantiles (4th quantile being the highest risk and 1st quantile being the lowest risk). During the period, 388 287 passengers were destined for 1297 airports in 168 countries or territories across the world. The risk index of 2019-nCoV among the countries had a very high correlation with the WHO-reported confirmed cases (0.97). According to our risk score classification, of the countries that reported at least one Coronavirus-infected pneumonia (COVID-19) case as of 5 February 2020, 24 countries were in the 4th quantile of the risk index, two in the 3rd quantile, one in the 2nd quantile and none in the 1st quantile. Outside China, countries with a higher risk of 2019-nCoV transmission are Thailand, Cambodia, Malaysia, Canada and the USA, all of which reported at least one case. In pan-Europe, UK, France, Russia, Germany and Italy; in North America, USA and Canada; in Oceania, Australia had high risk, all of them reported at least one case. In Africa and South America, the risk of transmission is very low with Ethiopia, South Africa, Egypt, Mauritius and Brazil showing a similar risk of transmission compared to the risk of any of the countries where at least one case is detected. The risk of transmission on 31 January 2020 was very high in neighbouring Asian countries, followed by Europe (UK, France, Russia and Germany), Oceania (Australia) and North America (USA and Canada). Increased public health response including early case recognition, isolation of identified case, contact tracing and targeted airport screening, public awareness and vigilance of health workers will help mitigate the force of further spread to naïve countries.

TI - [Epidemiologic](#) characteristics of early cases with 2019 novel coronavirus (2019-nCoV) disease in Korea.

AU - [Ki M](#)
AU - Task Force for 2019-nCoV

AB - In about 20 days since the diagnosis of the first case of the 2019 novel coronavirus (2019-nCoV) in Korea on January 20, 2020, 28 cases have been confirmed. Fifteen patients (53.6%) of them were male and median age of was 42 years (range, 20-73). Of the confirmed cases, 16, 9, and 3 were index (57.2%), first-generation (32.1%), and second-generation (10.7%) cases, respectively. All first-generation and second-generation patients were family members or intimate acquaintances of the index cases with close contacts. Fifteen among 16 index patients had entered Korea from January 19 to 24, 2020 while 1 patient had entered Korea on January 31, 2020. The average incubation period was 3.9 days (median, 3.0), and the reproduction number was estimated as 0.48. Three of the confirmed patients were asymptomatic when they were diagnosed. Epidemiological indicators will be revised with the availability of additional data in the future. Sharing epidemiological information among researchers worldwide is essential for efficient preparation and response in tackling this new infectious disease.

AB - The COVID-19 pandemic has rapidly moved telemedicine from discretionary to necessary. Here we describe how the Stanford Neurology Department: 1) rapidly adapted to the COVID-19 pandemic, resulting in over 1000 video visits within four weeks and 2) accelerated an existing quality improvement plan of a tiered roll out of video visits for ambulatory neurology to a full-scale roll out. Key issues we encountered and addressed were related to: equipment/software, provider engagement, workflow/triage, and training. Upon reflection, the key drivers of our success were provider engagement and a supportive physician champion. The physician champion played a critical role understanding stakeholder needs, including staff and physicians' needs, and creating workflows to coordinate both stakeholder groups. Prior to COVID-19, physician interest in telemedicine was mixed. However, in response to county and state stay-at-home orders related to COVID-19, physician engagement changed completely; all providers wanted to convert a majority of visits to video visits as quickly as possible. Rapid deployment of neurology video visits across all its subspecialties is feasible. Our experience and lessons learned can facilitate broader utilization, acceptance, and normalization of video visits for neurology patients in the present as well as the much anticipated post-pandemic era.

TI - Associations of stay-at-home order and face-masking recommendation with trends in daily new cases and deaths of laboratory-confirmed COVID-19 in the United States
PY - 2020
AU - Jie Xu
AU - Sabiha Hussain
AU - Guanzhu Lu
AU - Shi Wei
AU - Wei Bao
AU - Lanjing Zhang
AB - OBJECTIVE: To examine the associations of stay-at-home order and face-masking recommendation with trends in daily new cases and deaths of laboratory-confirmed coronavirus disease 2019 (COVID-19) in the United States DESIGN: Piecewise log-linear modelling of temporal trends with turning-points, followed by quasi-experimental study on trend turning-point. Simulation studies were carried out to understand the outcomes under the scenarios if early-implementation and removal of stay-at-home order occurred. SETTING: Population data in the United States PARTICIPANTS: Residents in the U.S., who were affected by the stay-at-home and face-masking policies MAIN OUTCOME MEASURES: Turning-points of the daily new cases and deaths of COVID-19, and COVID-19 time-varying reproduction numbers (Rt) in the U.S. RESULTS: The number and the proportion of U.S. residents under SAHO increased between March 19 and April 7, and plateaued at 29,0829,980 and 88.6%, respectively. The trend in COVID-19 daily cases reduced after March 23 (P<0.001) and further reduced on April 3 (P<0.001), which was associated with implementation of SAHO by 10 states on March 23, and the Centers for Disease Control and Preventions recommendation of face-masking, respectively. Similar turning points were identified in the trends of daily deaths with a lag time. The estimates of Rt based on the 3 reported mean serial-intervals of COVID-19 all started to decline on March 19, when SAHO was first implemented in the U.S. and declined faster after March 23. After a short plateau, Rt continued to decline after April 3 and fell below/around 1.0 on April 13. CONCLUSIONS: There were 2 turning points of COVID-19 daily new cases or deaths in the U.S., which appeared to associate with implementation of SAHO and the CDC face-masking recommendation. Simulation on early-implementation and removal of SAHO reveals considerable impact on COVID-19 daily new cases and deaths. These findings may inform decision-making of lifting SAHO and face.

Report on the Epidemiological Features of Coronavirus Disease 2019 (COVID-19) Outbreak in the Republic of Korea from January 19 to March 2, 2020

1939 Selected Export Clear

What does this address and what it does not address

- It is a proof of concept for and approach to:
 - Obtaining meta-data for records from existing repositories
- It does not address:
 - Comprehensive searching (retrieving all references from all databases)
 - Federated searching (searching multiple databases at the same time)
 - De-duplication, or finding references unique to each repository
- It is a starting, not final point

Another use case

- Identifying the most current and comprehensive living review on social distancing
 - If repositories of living review on social distancing were allowing extraction of meta-data (eg # of trials included, search end date) in a RIS-like format (e.g. COCA FHIR)
 - If one had a tool to combine/compare the RIS
- The task would be solved

Why Improve my RIS is important?

- Because the problem in achieving most of our goals is not technical (how to handle the data), but political (willingness to share data).
- Choosing a simple solution offers a cheap way of proofing the concept that data can be AND ARE shared
- Improve my RIS would provide pilot data for fundraising

I can add the Epistemikos/L·OVE part.

Is it OK if I upload to google docs and edit there?

I would paste screenshots following the following script

- 1 - Paste in Epistemikos 'improve my RIS' a list of PMID from your example (this is the preliminary URL [limited to 100 IDs by now]: https://www.epistemikos.org/documents/check_documents)
- 2 - Return the % of articles from that list that are in our database
- 3- Export a RIS with the following metadata in M3 field (the same you are using): Primary study/ RCT or non- RCT / reports data or does not report data.

Then,

Starting from the question of the example review in

L·OVE: https://app.iloveevidence.com/loves/5e6fdb9669c00e4ac072701d?question_domain=5b1dcd8ae611de7ae84e8f14&population=5e7fce7e3d05156b5f5e032a&intervention=5e93a6fc3552583c288cc9c7

- 1- Export a RIS
 - 2- (I would not explain again how to go get from RIS to list of PMIDs)
 - 3- Paste list of IDs in Cochrane Register
- End of demo --

Any suggestion is more than welcome

Gabriel
